### Tracheostomy and Ventilator Dependence: Overview

Tracheostomy and Ventilator Dependence is a text written for speech-language pathologists who are involved in the care of patients with long-term tracheostomy, ventilator dependency, or both. The book discusses the care of patients with various causes for their respiratory insufficiency, but the text is slanted toward the care of cognitively intact, long-term ventilator-dependent patients, such as those suffering from high cervical spinal cord injuries.

Talking tracheostomy: allows for voicing while tracheostomy tube cuff remains inflated (these patients are often ventilator dependent) with use of separate air sources for ventilation and phonation. Specialty cannula: allows for voicing while tracheostomy tube cuff remains inflated (e.g., speech cannula with flaps for directing exhaled air to the upper airway).

### Tracheostomy and Ventilator Dependence

Abstract. As the population of ventilator-dependent children with tracheostomies grows, there are increasing demands to shift the care of technology-dependent children from hospital to home. Home care nurses are an integral part in the continuum of care for these children and their families after hospital discharge.

Clinical experience with PO intake and tracheostomy/ventilator dependent patients has shown that PO intake is best assessed in a patient that is hemodynamically stable, tolerating their ventilator settings, is alert with manageable secretions, and can tolerate some level of tracheostomy tube cuff deflation.

### Dysphagia in tracheostomy and ventilator-dependent patients

A long-term ventilator-dependent patient will almost always have a tracheotomy (trach) tube—a vent tube placed surgically through an incision at the front of the neck into the trachea, or windpipe. Trach tubes are inserted while the patient is sedated but are used for people who will be awake. Bands going around the neck hrmally.

### 5 Facts About Being a Ventilator-Dependent Patient

"Avoid tracheotomy in COVID-19 positive or suspected patients during periods of respiratory instability or heightened ventilator dependence." "Tracheotomy can be considered in patients with stable pulmonary status but should not take place sooner than 2-3 weeks from intubation and, preferably, with negative Covid-19 testing.

Tracheostomy and transtracheal injections should be avoided because of possible ossification in the incision and resultant airway obstruction. However, there is a recent report of emergent tracheostomy in a child with FOP. Airway endoscopy mask was chosen for simultaneous noninvasive ventilation and fiber-optic intubation.

### Emergent airway management in a case of fibrodysplasia ...

The effect of various airway management strategies, such as the timing of tracheostomy, on liberation from mechanical ventilation (MV) is uncertain. We tested the hypothesis that tracheostomy, when performed prior to active weaning, does not influence the duration of weaning or of MV in comparison with a more selective use of tracheostomy.

Adults who are tracheotomy and ventilator dependent or who are undergoing prolonged weaning are some of the most challenging patients in the caseload of an SLP. Airway issues influence many aspects of patient care, including swallowing. The medical issues for patients with these complex cases greatly affect their rehabilitation.
